```
Python object system:
Idea: All bank accounts have a balance and an account holder;
the Account class should add those attributes to each of its instances
                         >>> a = Account('Jim')
  A new instance is
                         >>> a.holder
 created by calling a
                         'Jim'
        class
                         >>> a.balance
                                                 An account instance
When a class is called:
                                                          holder: 'Jim'
                                            balance: 0
1.A new instance of that class is created:
2. The __init__ method of the class is called with the new object as its first
 argument (named self), along with any additional arguments provided in the
  call expression.
                     class Account:
                             __init__(self, account_holder):
                        ⊳def
   init is called a
                             self.balance = 0
     constructor
                             self.holder = account_holder
                         def deposit(self, amount)
                             self.balance = self.balance + amount
                             return self.balance
 self should always be
                             withdraw(self, amount):
  if amount > self.balance:
    return 'Insufficient funds'
                         def
bound to an instance of
 the Account class or a
  subclass of Account
                             self.balance = self.balance - amount
                             return self.balance
                      >>> type(Account.deposit)
 Function call: all
                      <class 'function'
                      >>> type(a.deposit)
  arguments within
    parentheses
                      <class 'method'>
                       Account deposit(a, 5)
 Method invokation:
  One object before
                          a.deposit(2)
  the dot and other
                                                  Call expression
  arguments within
     parentheses
                           Dot expression
                           <expression> . <name>
The <expression> can be any valid Python expression.
The <name> must be a simple name.
Evaluates to the value of the attribute looked up by <name> in the object
that is the value of the <expression>.
To evaluate a dot expression:
   Evaluate the <expression> to the left of the dot, which yields
     the object of the dot expression
     <name> is matched against the instance attributes of that object;
     if an attribute with that name exists, its value is returned
    If not, <name> is looked up in the class, which yields a class
     attribute value
     That value is returned unless it is a function, in which case a
     bound method is returned instead
 Assignment statements with a dot expression on their left-hand side affect
 attributes for the object of that dot expression
 • If the object is an instance, then assignment sets an instance attribute
 • If the object is a class, then assignment sets a class attribute
          Account class

                                         0.08
>>> jim_account.interest
0.04
class CheckingAccount(Account):
       "A bank account that charges for withdrawals."""
     withdraw fee = 1
     interest = 0.01
    return (super().withdraw(
                                       amount + self.withdraw_fee)
 To look up a name in a class:
 1. If it names an attribute in the class, return the attribute value.
 2. Otherwise, look up the name in the base class, if there is one.
 >>> ch = CheckingAccount('Tom') # Calls Account.__init_
 >>> ch.interest
                     # Found in CheckingAccount
 0.01
 >>> ch.deposit(20) # Found in Account
 20
 >>> ch.withdraw(5) # Found in CheckingAccount
```
